Lab 3 – Create a reusable pipeline

The pipeline you built in Lab 2 copied a file from a website – GitHub – into your data lake. In this lab you will use linked service and dataset parameters in combination with ADF pipeline expressions to make a reusable pipeline – a single pipeline that can perform this task for any of the AdventureWorks files stored in GitHub.

Lab 3.1 – Create a generic HTTP linked service & dataset

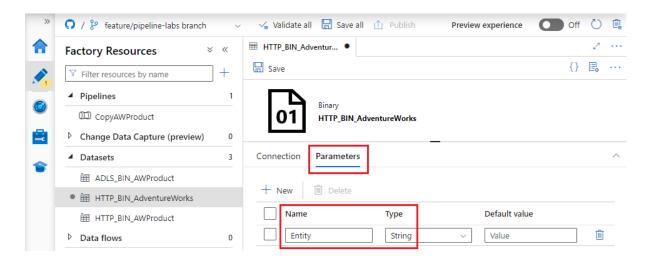

In Lab 2.1 you created a linked service containing the full URL path to the AdventureWorks "Products.csv" file. We'll improve upon that by creating a linked service and dataset that can refer to any of the AdventureWorks sample files on GitHub.

- 1. Navigate to the management hub in ADF Studio, open the "Linked services" page and click "+ New". Choose a linked service of type "HTTP" and click "Continue".
- 2. Configure the linked service like this:
 - Give it the Name "HTTP_GitHubAW".
 - Set its Base URL to "<a href="https://raw.githubusercontent.com/microsoft/sql-server-samples/master/samples/databases/adventure-works/oltp-install-script/". This is the first part of the URL you used in Lab 2.1 it identifies the folder containing AdventureWorks data files.
 - Set Authentication type to "Anonymous".
 - Click "Create".
- 3. Navigate to the authoring canvas and use the "Dataset Actions" menu to create a new dataset.
 - Choose the "HTTP" data store.
 - Choose the "Binary" file format.
 - Name the dataset "HTTP_BIN_AdventureWorks", and select the new "HTTP_AWGitHub" linked service.
 - Leave "Relative URL" blank again we will come back to it in a moment and click OK.
 - Save the new dataset.
- 4. To reuse the dataset, we need to be able to pass in different relative URL values at runtime, depending which file is required. We can do this using a dataset parameter. Use the "Parameters" configuration tab to create a new String parameter called "Entity".

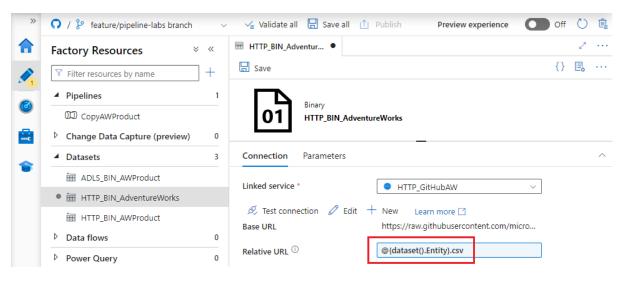

Microsoft Data Integration Pipelines – SQLBits 2024

5. To use the runtime parameter value, the relative URL will require a pipeline expression to reference the parameter. Furthermore, as every file in the collection has a ".csv" extension, we can include that in the expression (and save users of the pipeline from having to specify the same extension repeatedly).

Enter an expression to achieve this in the "Connection" tab's "Relative URL" field. A possible implementation is <code>@{dataset().Entity}.csv</code> – this expression uses string interpolation to avoid a less readable <code>@concat</code> function call.

6. Use the "Save all" button to commit your changes to GitHub.

Lab 3.2 – Create a generic data lake dataset

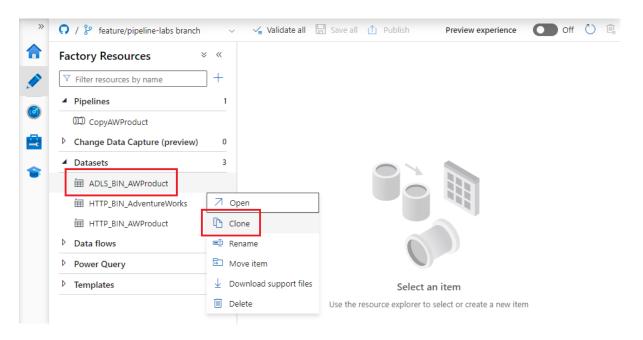

By parameterising the HTTP dataset you created in Lab 3.1, you enabled it to accept different file names at runtime. We need now to perform the equivalent task for the data lake dataset.

1. Create a new dataset, this time by cloning the "ADLS_BIN_AWProduct" dataset created in Lab 2. Locate the dataset in the "Factory Resources" menu, then use the "Clone" option on its "Actions" menu.

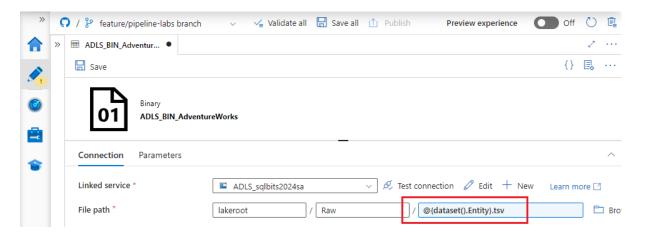

Microsoft Data Integration Pipelines - SQLBits 2024

- 2. Rename the cloned dataset "ADLS_BIN_AdventureWorks"
- 3. Create a dataset parameter, called "Entity" and of type String.
- 4. Replace "Product.csv" in the "File name" section of the "Connection" tab's "File path" with an expression. In the screenshot we have changed the extension of the data lake file to "tsv", to indicate that the file is tab-separated.

5. Commit your changes to GitHub.

Lab 3.3 – Create a generic pipeline

A pipeline using the two datasets you have created must provide runtime values for their parameters. Instead of hard-coding them into the pipeline definition, use pipeline parameters to make the pipeline generic as well.

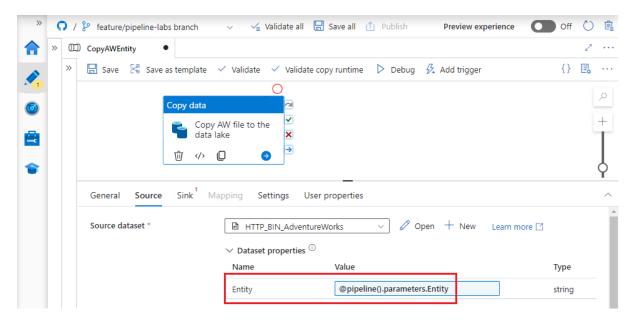

- 1. Create a new ADF pipeline called "CopyAWEntity"
- 2. On the pipeline's "Parameters" tab, create a String parameter called "Entity".
- 3. Drag a "Copy" activity from the "Move & transform" section of the activity toolbox and drop it onto the design surface. Give the activity a meaningful name.

Microsoft Data Integration Pipelines - SQLBits 2024

4. On the activity's "Source" tab, choose dataset "HTTP_BIN_AdventureWorks". A field in which to specify the **dataset**'s parameter value will appear – supply an expression to pass in the **pipeline** parameter value.

The expression in the screenshot passes the pipeline's parameter value without modification – the file extension will be appended by the "HTTP_BIN_AdventureWorks" dataset.

- 5. Configure the activity's "Sink" tab similarly, choosing dataset "ADLS_BIN_AdventureWorks" and passing the pipeline's parameter value to the dataset.
- 6. Save your changes, then run the pipeline in "Debug" mode, specifying an appropriate parameter value, e.g.:
 - BillOfMaterials
 - BusinessEntity
 - ContactType

Verify that the expected filenames and contents appear in the data lake's "Raw" folder.

Lab 3.4 – Reuse the generic pipeline

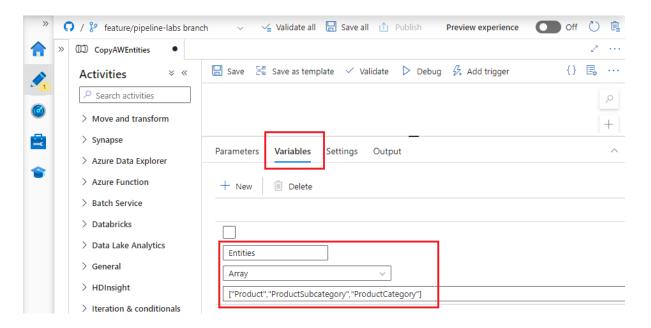

Your generic pipeline can be used to extract any ".csv" file from the AdventureWorks sample data folder on GitHub. In this lab you will automate the extraction of multiple files.

- 1. Create a new pipeline called "CopyAWEntities".
- 2. The new pipeline will store a list of entities in an array variable, then use a ForEach activity to iterate over the array. Use the pipeline's "Variables" configuration tab to create an array variable with default value ["Product", "ProductSubcategory", "ProductCategory"].

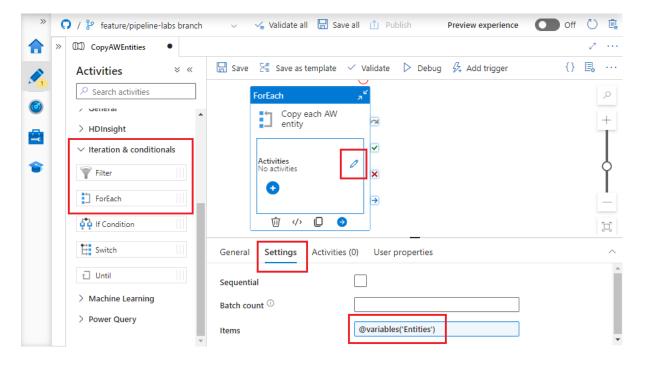

Microsoft Data Integration Pipelines - SQLBits 2024

3. Drag a ForEach activity from the "Iteration & conditionals" section of the Activities toolbox and onto the design surface. Use its "Settings" tab to configure the "Items" collection – this is the collection of items over which the activity will iterate.

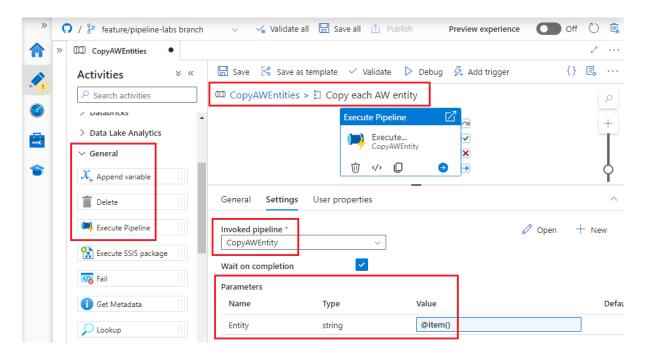

- 4. Click the "pencil" icon on the ForEach activity (indicated in the screenshot) to open the subpipeline to be executed at each iteration. Drag an "Execute Pipeline" activity found in the "General" section of the Activities toolbox onto the sub-pipeline design surface and name it appropriately.
- 5. Configure the activity to call the generic "CopyAWEntity" pipeline. A value is required for that pipeline's "Entity" parameter use the @item() function to refer to the array element being considered during a given iteration.

Microsoft Data Integration Pipelines – SQLBits 2024

- 6. Save your changes and run the pipeline. When you run the pipeline using "Debug", ADF Studio warns you that the ForEach activity will handle its input collection sequentially. This is a debug-specific feature default ForEach behaviour in published pipelines is to handle array elements in parallel. This makes the activity a powerful way to execute multiple data processing activities simultaneously.
- 7. When the pipeline's execution has successfully completed, inspect the "lakeroot" container's "Raw" folder to verify that it now contains the three Product.tsv, ProductSubcategory.tsv and ProductCategory.tsv files.

Recap

In Lab 3 you:

- created reusable datasets to represent different source and data lake files generically
- created a generic pipeline using those generic datasets
- reused the generic pipeline in a ForEach activity, enabling a single pipeline to download three source files using the same set of activities.
